In c++ is there any way i can serialize a function and set it through a socket to other application with identical binary and have it interpeded there?

Great question! You're asking if in C++ you can **serialize a function (its code)**, send it over a socket to another application with the same binary, and then have the remote side execute it.

Short answer:

No, not directly and not in standard C++.

Why?

1. Functions are not first-class serializable objects.

You can't just serialize a function pointer or code because the binary layout of functions is generally not designed for that. Function pointers are addresses in memory — just sending that pointer to another process won't work (the address won't be valid there).

2. Code relocation and security issues:

Modern OSes use address space layout randomization (ASLR), and the code segment is typically read-only and not writable, so sending raw machine code to be executed remotely is tricky and risky.

3. Cross-process/function serialization is not built-in:
